HIGH-TEMPERATURE PROGRAMMABLE SHUNT REGULATOR

FEATURES

▲ Adjustable output voltage from 2.5V to 35V.
▲ Operational beyond the -60°C to +230°C temperature range.
▲ Low dynamic output impedance.
▲ Sink current capability 500µA to 50mA
▲ Low temperature coefficient (\(\Delta V_{REF}=35\text{mV}\) typ).
▲ 2.55V reference with 6% accuracy.
▲ Fast turn-on response.
▲ Shut-down mode.
▲ Stable over a continuous range of load capacitors (27nF min).
▲ Monolithic design.
▲ Ruggedized SMT and thru-hole packages.
▲ Also available as tested bare die.

APPLICATIONS

▲ Reliability-critical, Automotive, Aeronautics & Aerospace, Down-hole.
▲ Shunt regulators, voltage clamping, voltage references, voltage regulators, switching regulators, feedback networks, voltage monitors, current sources.

DESCRIPTION

XTR431 is a high-reliability, high-temperature version of the well known "431" shunt voltage regulator. It operates as a 3-terminal shunt regulator with an total drift of the reference voltage as low as 35mV (typical). The output voltage may be set from 2.55V to 35V by selecting the value of two external resistors implementing a divider network.

The XTR431 is able to reliably operate over a wide range of currents from 500µA to 50mA and load capacitors from 27nF and up. Functionality features include shut-down mode and low dynamic output impedance.

This part can be used as a high-reliability, high-temperature replacement of zener diodes in many applications such as onboard regulation, adjustable power supply and switching power supplies. The fact of operating as a zener diode makes the XTR431 convenient to be used as a positive or negative regulator.

Special design techniques were used allowing the XTR431 parts to offer a precise, robust and reliable operation in critical applications. Full functionality is guaranteed from -60°C to +230°C, though operation well below and above this temperature range is achieved.

The XTR431 has been designed to reduce system cost and ease adoption by reducing the learning curve and providing smart and easy to use features.

XTR431 is available in ruggedized SMT and thru-hole packages. Parts are also available as tested bare dies.

**THEORY OF OPERATION**

**Introduction**
The XTR431 is a SOI CMOS shunt voltage regulator able to operate from -60°C to +230°C, with voltages from 2.5V to 35V. As the XTR431 is built in a pure CMOS process, its internal structure is well different from those using BJTs in other commercial versions of the "431". This fact is mainly observed on the minimum operating voltage, stability behavior, in the start-up timing characteristics, as well as in the small reference and leakage currents.

The following image shows the typical shunt regulator application with external components. Capacitor C1 represents the parasitic capacitance between VREF and ANODE due to packaging and PCB routing. In cases where the parasitic capacitance C1 is above some tens of picofarads, a compensation capacitor C2 of some nanofarads may be needed. Capacitor Cout connected between ANODE and CATHODE is always needed.

**General Considerations**

**Thermal considerations**
The XTR431 has no internal thermal shutdown feature, allowing it to operate even above the -60°C to +230°C range. The user must ensure that the junction temperature will not exceed the temperature defined in the Absolute Maximum Ratings section for long periods and remain within the recommended temperature range whenever possible. Functionality can be demonstrated for temperatures well above 300°C (contact X-REL Semiconductor for further information).

Notice that above 200°C the VREF input current increases, resulting in an increase of the VREF voltage (IREF increase is equal to RV \* IREF). This further increases the dissipated power which in turns increases the junction temperature. The value of R1 should therefore not be too large when the circuit is expected to operate at high cathode voltage and current.

**Ground connection**
The XTR431 anode pin should always be connected to the lower rail of the supply prior applying a cathode voltage. Accidental disconnecting of the anode under operation could damage the part.

**Stability conditions**
Conversely to BJT commercial versions of the "431", the XTR431 presents a continuous range of possible load capacitors. This range has minimum values which vary with the output cathode voltage, cathode current and operating temperature. This minimum load capacitance can be as low as 10nF for \( I_{\text{KA}} \leq 1 \text{mA} \) and temperatures above 25°C, though a minimum "one-fits-all" value of 27nF can be used for whatever cathode current and temperature condition.

If due to the layout of the substrate (ceramic or PCB) where the XTR431 is used, the parasitic capacitance \( (C_p) \) between VREF and ANODE is large (some tens of pF), extra compensation capacitor C1 (1-10nF) may be needed.

**Functional Features & Operation**

**Disable feature**
Whenever the VREF terminal is pulled down below its internal 2.5V reference \( (/EN \text{ in the image below is high}) \), the cathode current \( I_{\text{KA}} \) is quickly turned off. This means that, after this event, \( V_{\text{KA}} \) reaches the \( V_N \) voltage.

When the circuit is enabled back again \( (/EN \text{ is low}) \), VREF will go up depending on \( R_1, R_2, C_p \) and \( C_1 \) values. VREF will then go to its steady state value of 2.5V once the cathode current settles again. A safe limit for \( |dV_{\text{REF}}/dt| \) is not to exceed 0.2V/\( \mu \text{s} \). Assuming that initially \( V_{\text{KA}}=V_N \).

\[
\frac{dV_{\text{REF}}}{dt} \approx \frac{V_N}{R_1 \cdot C_1} < 0.2 V/\mu \text{s}
\]

With \( R_1 \) fixed, the previous relation gives a minimum recommended \( C_1 \) value when the Enable functionality is used.
